Economic Growth, the High-Tech Sector, and the High Skilled: Theory and Quantitative Implications

Pedro Mazeda Gil, Óscar Afonso, Paulo Brito

Faculty of Economics, Univ. Porto, and ISEG, Univ. Lisboa, Portugal

23 Feb 2016 – GPEARl & GEE
Europe 2020 Strategy rests on the conventional view that increases in the shares of high-skilled workers and of the high-tech sector are major intermediate goals to improve the economic growth rate of the European Union.
Europe 2020 Strategy rests on the conventional view that increases in the shares of high-skilled workers and of the high-tech sector are major intermediate goals to improve the economic growth rate of the European Union.

One of the 2020 headline targets of the Europe 2020 Strategy states that “… at least 40% of the younger generation (30-34 years old) should have a tertiary degree.”
Europe 2020 Strategy rests on the conventional view that increases in the shares of high-skilled workers and of the high-tech sector are major intermediate goals to improve the economic growth rate of the European Union.

- One of the 2020 headline targets of the Europe 2020 Strategy states that “... at least 40% of the younger generation (30-34 years old) should have a tertiary degree.”

- Another major target is to reduce the gap over the relative importance of the high-tech sector as compared with the US (EC, 2010).
However, cross-country evidence for Europe shows there is a weak relationship between the economic growth rate and both the skill structure and the technology structure (relative production or relative number of firms in the high-tech vis-à-vis the low-tech sector):

- Growth-skill elasticity of $-0.026$ (s.e. of 0.172);
- Growth-production elasticity of $-0.003$ (s.e. of 0.118).
However, cross-country evidence for Europe shows there is a weak relationship between the economic growth rate and both the skill structure and the technology structure (relative production or relative number of firms in the high-tech vis-à-vis the low-tech sector):

- Growth-skill elasticity of $-0.026$ (s.e. of 0.172);
- Growth-production elasticity of $-0.003$ (s.e. of 0.118).

**Figure 1.**
But there is a significant positive relationship between the technology structure and the skill structure: relative production-skill elasticity of 0.430 (s.e. of 0.160);
Motivation & Empirical evidence (III)

- But there is a significant positive relationship between the technology structure and the skill structure: relative production-skill elasticity of 0.430 (s.e. of 0.160);
- Relative-production elasticity is higher than relative-number-of-firms elasticity $\Rightarrow$ relative firm size also exhibits a positive elasticity w.r.t the skill structure.
But there is a significant positive relationship between the technology structure and the skill structure: relative production-skill elasticity of 0.430 (s.e. of 0.160);

Relative-production elasticity is higher than relative-number-of-firms elasticity ⇒ relative firm size also exhibits a positive elasticity w.r.t the skill structure.

Figure 2.
Thus, the conventional view underlying Europe’s “2020 Strategy” is not fully supported by the data.
Thus, the conventional view underlying Europe’s “2020 Strategy” is not fully supported by the data.

What can explain that? Are there any policy instruments that would allow for all the “right” correlations?
Thus, the conventional view underlying Europe’s “2020 Strategy” is not fully supported by the data.

What can explain that? Are there any policy instruments that would allow for all the “right” correlations?

The available literature does not provide an answer if we consider all the three elasticities (and the two variants using the data on production and the number of firms).
Our paper

- **Analytics**: we adopt an agnostic approach by extending a benchmark endogenous growth model (e.g., Acemoglu and Zilibotti, 2001) with a very flexible structure.
  - Allows us to **identify the structural relationships** between growth, technology structure and skill structure underlying the cross-country data.
Our paper

- **Analytics**: we adopt an agnostic approach by extending a benchmark endogenous growth model (e.g., Acemoglu and Zilibotti, 2001) with a very flexible structure.
  - Allows us to **identify the structural relationships** between growth, technology structure and skill structure underlying the cross-country data.

- **Quantification**: we find consistency with the empirical relationships if we allow for the simultaneous existence of:
  - **Some scale effects on growth** (associated with positive but small market-complexity costs in vertical R&D);
  - **High barriers to entry into the high-tech vis-à-vis the low-tech sector** (associated with relatively large fixed R&D costs in the high-tech sector).
A competitively-produced **final good** can be used in consumption, intermediate-goods production and R&D;

Model (I): setup
A competitively-produced **final good** can be used in consumption, intermediate-good production and R&D;

The final good is produced using either **low-** or **high-skilled labour** and a continuum of differentiated **labour-specific intermediate goods**;
Model (I): setup

- A competitively-produced **final good** can be used in consumption, intermediate-good production and R&D;
- The final good is produced using either low- or high-skilled labour and a continuum of differentiated labour-specific intermediate goods;
- R&D is of two types (**vertical or horizontal**) and can be directed to one of the two types of labour-specific intermediate goods;
Model (I): setup

- A competitively-produced **final good** can be used in consumption, intermediate-good production and R&D;
- The final good is produced using either **low-** or **high-skilled labour** and a continuum of differentiated **labour-specific intermediate goods**;
- **R&D** is of two types (**vertical** or **horizontal**) and can be **directed** to one of the two types of labour-specific intermediate goods;
- The economy is populated by a fixed number of infinitely-lived **households** who inelastically supply either low- or high-skilled labour;
Model (I): setup

- A competitively-produced final good can be used in consumption, intermediate-good production and R&D;
- The final good is produced using either low- or high-skilled labour and a continuum of differentiated labour-specific intermediate goods;
- R&D is of two types (vertical or horizontal) and can be directed to one of the two types of labour-specific intermediate goods;
- The economy is populated by a fixed number of infinitely-lived households who inelastically supply either low- or high-skilled labour;
- Households make consumption decisions and invest in firms’ equity.
In the model: “sector” represents a group of firms producing the same type of labour-specific intermediate goods.
In the **model**: “sector” represents a group of firms producing the same type of labour-specific intermediate goods.

**The data** shows that the high-tech sectors are more intensive in high-skilled labour than the low-tech sectors (30.9% vs. 12.1%);
Model (II): setup

- In the **model**: “sector” represents a group of firms producing the same type of labour-specific intermediate goods.

- **The data** shows that the high-tech sectors are more intensive in high-skilled labour than the low-tech sectors (30.9% vs. 12.1%);

  \[\downarrow\]

- Assumption: the **high- and low-skilled labour-specific intermediate-good sectors in the model** → theoretical counterpart of the **high- and low-tech sectors in the data** (e.g., Cozzi and Impuliti, 2010).
Model (III): final-good production function

For firm $n$ in the final-good sector at time $t$:

$$Y(n, t) = \left[ \int_0^{N_L(t)} (\lambda j_L(\omega_L, t) \cdot X_L(n, \omega_L, t))^{1-\alpha} d\omega_L \right] \times [(1 - n) \cdot l \cdot L(n)]^\alpha +$$

$$+ \left[ \int_0^{N_H(t)} (\lambda j_H(\omega_H, t) \cdot X_H(n, \omega_H, t))^{1-\alpha} d\omega_H \right] \times [n \cdot h \cdot H(n)]^\alpha$$

where:
Model (III): final-good production function

- For firm $n$ in the final-good sector at time $t$:

$$Y(n, t) = \left[ \int_0^{N_L(t)} (\lambda j_L(\omega_L, t) \cdot X_L(n, \omega_L, t))^{1-\alpha} \, d\omega_L \right] [(1 - n) \cdot l \cdot L(n)]^\alpha + \left[ \int_0^{N_H(t)} (\lambda j_H(\omega_H, t) \cdot X_H(n, \omega_H, t))^{1-\alpha} \, d\omega_H \right] [n \cdot h \cdot H(n)]^\alpha$$

where:

- Number of varieties in the $m$-specific intermediate-good sector: $N_m(t), m \in \{L, H\}$;
Model (III): final-good production function

For firm $n$ in the final-good sector at time $t$:

$$Y(n, t) = \left[ \int_0^{N_L(t)} (\lambda j_L(\omega_L, t) \cdot X_L(n, \omega_L, t))^{1-\alpha} d\omega_L \right] [(1 - n) \cdot l \cdot L(n)]^\alpha + \left[ \int_0^{N_H(t)} (\lambda j_H(\omega_H, t) \cdot X_H(n, \omega_H, t))^{1-\alpha} d\omega_H \right] [n \cdot h \cdot H(n)]^\alpha$$

where:

- Number of varieties in the $m$-specific intermediate-good sector: $N_m(t), m \in \{L, H\}$;
- Quality level of an existing variety in the $m$-specific intermediate-good sector: $j_m(t)$;
Model (III): final-good production function

For firm $n$ in the final-good sector at time $t$:

$$Y(n, t) = \left[ \int_{0}^{N_L(t)} (\lambda_i L(\omega_L, t) \cdot X_L(n, \omega_L, t))^{1-\alpha} d\omega_L \right] [(1 - n) \cdot l \cdot L(n)]^{\alpha} + \left[ \int_{0}^{N_H(t)} (\lambda_i H(\omega_H, t) \cdot X_H(n, \omega_H, t))^{1-\alpha} d\omega_H \right] [n \cdot h \cdot H(n)]^{\alpha}$$

where:

- Number of varieties in the $m$-specific intermediate-good sector: $N_m(t), m \in \{L, H\}$;
- Quality level of an existing variety in the $m$-specific intermediate-good sector: $j_m(t)$;
- Absolute-productivity advantage of $H$ over $L$ implies $h > l \geq 1$. 

Horizontal R&D increases the number of varieties / firms, $N_m(t)$, $m \in \{L, H\}$, in the $m$-specific intermediate-good sector, according to:

$$
\dot{N}_m(t) = R_{h,m}(t) \frac{1}{\phi_m \cdot m^\delta \cdot N_m(t)^{\sigma} / F_{h,m}},
$$

where:
Model (IV): horizontal R&D

- **Horizontal R&D** increases the number of varieties / firms, $N_m(t)$, $m \in \{L, H\}$, in the $m$-specific intermediate-good sector, according to:

$$\dot{N}_m(t) = R_{h,m}(t) \frac{1}{\phi_m \cdot m^\delta \cdot N_m(t)^\sigma / F_{h,m}},$$

where:

- Instantaneous flow of new IG: $\dot{N}_m$; horizontal R&D expenditure: $R_{h,m}$;
Model (IV): horizontal R&D

- **Horizontal R&D** increases the number of varieties / firms, $N_m(t)$, $m \in \{L, H\}$, in the $m$-specific intermediate-good sector, according to:

$$\dot{N}_m(t) = R_{h,m}(t) \frac{1}{\phi_m \cdot m^\delta \cdot N_m(t)^\sigma / F_{h,m}},$$

where:

- Instantaneous flow of new IG: $\dot{N}_m$; horizontal R&D expenditure: $R_{h,m}$;
- **Flow fixed cost**: $\phi_m \Rightarrow \text{relative barriers to (horizontal) entry}$: $\phi_{H}/\phi_{L}$;
Model (IV): horizontal R&D

- **Horizontal R&D** increases the number of varieties / firms, \( N_m(t) \), \( m \in \{L, H\} \), in the \( m \)-specific intermediate-good sector, according to:

\[
\dot{N}_m(t) = R_{h,m}(t) \frac{1}{\phi_m \cdot m^\delta \cdot N_m(t)^\sigma / F_{h,m}},
\]

where:

- **Instantaneous flow of new IG**: \( \dot{N}_m \); horizontal R&D expenditure: \( R_{h,m} \);
- **Flow fixed cost**: \( \phi_m \Rightarrow \text{relative barriers to (horizontal) entry} \): \( \phi_H / \phi_L \);
- **Market complexity cost factor**: \( m^\delta \), \( \delta \in \mathbb{R} \).
Vertical R&D increases the quality level, \( j_m(t), m \in \{L, H\} \), of the good of an existing industry in the \( m \)-specific intermediate-good sector, according to:

\[
I_m(j_m) = R_{v,m}(j_m) \cdot \frac{1}{\zeta_m \cdot m^\epsilon \cdot q_m(j_m + 1)/F_{v,m}},
\]

where:

- Poisson arrival rate: \( I_m \);
- Vertical R&D expenditure: \( R_{v,m} \);
- Flow fixed cost: \( \zeta_m \)
  - relative barriers to (vertical) entry: \( \zeta_H/\zeta_L \);
- Market complexity cost factor: \( m^\epsilon \), \( \epsilon \in \mathbb{R} \)
  - net scale effects on growth: \( 1 - m^\epsilon \).
Model (V): vertical R&D

- **Vertical R&D** increases the quality level, $j_m(t)$, $m \in \{L, H\}$, of the good of an existing industry in the $m$-specific intermediate-good sector, according to:

$$I_m(j_m) = R_{v,m}(j_m) \cdot \frac{1}{\zeta_m \cdot m^\epsilon \cdot q_m(j_m + 1)/F_{v,m}},$$

where:

- Poisson arrival rate: $I_m$; vertical R&D expenditure: $R_{v,m}$;
Model (V): vertical R&D

- **Vertical R&D** increases the quality level, \( j_m(t) \), \( m \in \{L, H\} \), of the good of an existing industry in the \( m \)-specific intermediate-good sector, according to:

\[
I_m(j_m) = R_{v,m}(j_m) \cdot \frac{1}{\zeta_m \cdot m^\epsilon \cdot q_m(j_m + 1)/F_{v,m}},
\]

where:

- Poisson arrival rate: \( I_m \); vertical R&D expenditure: \( R_{v,m} \);
- **Flow fixed cost**: \( \zeta_m \Rightarrow \text{relative barriers to (vertical) entry} : \frac{\zeta_H}{\zeta_L} \);
Model (V): vertical R&D

- **Vertical R&D** increases the quality level, \( j_m(t) \), \( m \in \{L, H\} \), of the good of an existing industry in the \( m \)-specific intermediate-good sector, according to:

\[
I_m(j_m) = R_{v,m}(j_m) \cdot \frac{1}{\zeta_m \cdot m^\epsilon \cdot q_m(j_m + 1)/F_{v,m}},
\]

where:

- Poisson arrival rate: \( I_m \); vertical R&D expenditure: \( R_{v,m} \);
- Flow fixed cost: \( \zeta_m \) ⇒ **relative barriers to (vertical) entry**: \( \zeta_H/\zeta_L \);
- Market complexity cost factor: \( m^\epsilon, \epsilon \in \mathbb{R} \) ⇒ **net scale effects on growth**: \( 1 - \epsilon \).
Analytical results (I): BGP growth and skill structure

\[ \mathcal{E}_{H/L}^\tilde{g}(\epsilon, \zeta) = (1 - \epsilon) \left( \frac{h/l \cdot (H/L)^{1-\epsilon}}{\zeta / F_v + h/l \cdot (H/L)^{1-\epsilon}} \right), \quad \zeta \equiv \frac{\zeta_H}{\zeta_L}. \]
Analytical results (I): BGP growth and skill structure

\[ \mathcal{E}_{\tilde{g}}(\epsilon, \zeta) = (1 - \epsilon) \left( \frac{h/l \cdot (H/L)^{1-\epsilon}}{\zeta/F_v + h/l \cdot (H/L)^{1-\epsilon}} \right), \quad \zeta = \frac{\zeta_H}{\zeta_L}. \]

Figure 3. Curves \( \mathcal{E}_{\tilde{g}}(\epsilon, \zeta) = 0.025 \) and \( \mathcal{E}_{\tilde{g}}(\epsilon, \zeta) = 0.15 \).
Analytical results (II): BGP technology structure and skill structure

- Relative number of firms:

$$\tilde{N} \equiv \left( \frac{\tilde{N}_H}{N_L} \right) = Z_0 \cdot \left( \frac{H}{L} \right)^{D_0} \cdot \Omega(F_v, F_h),$$

$$D_0 \equiv (1 - \epsilon - \delta)/(\sigma + 1)$$

$$Z_0 \equiv (h/l)^{\frac{1}{\sigma+1}} \phi^{\frac{-1}{\sigma+1}} \zeta^{\frac{-1}{\sigma+1}}, \phi \equiv \frac{\phi_H}{\phi_L}, \zeta \equiv \frac{\zeta_H}{\zeta_L}$$
Analytical results (II): BGP technology structure and skill structure

- **Relative number of firms:**

  \[ \tilde{N} \equiv \left( \frac{\tilde{N}_H}{\tilde{N}_L} \right) = Z_0 \cdot \left( \frac{H}{L} \right)^{D_0} \cdot \Omega(F_v, F_h), \]

  \[ D_0 \equiv \frac{(1 - \epsilon - \delta)}{\sigma + 1} \]

  \[ Z_0 \equiv (h/l)^{\frac{1}{\sigma+1}} \phi^{-\frac{1}{\sigma+1}} \zeta^{-\frac{1}{\sigma+1}}, \phi \equiv \frac{\phi_H}{\phi_L}, \zeta \equiv \frac{\zeta_H}{\zeta_L} \]

- **Relative production:**

  \[ \tilde{X} \equiv \left( \frac{\tilde{X}_H}{\tilde{X}_L} \right) = Z_1 \cdot \left( \frac{H}{L} \right)^{D_1} \cdot \Omega(F_v, F_h), \]

  \[ D_1 \equiv \{ \alpha \delta + 1 - \alpha + \sigma - \epsilon [1 + (1 + \alpha) \sigma] \} / [(\sigma + 1)(1 - \alpha)] \]

  \[ Z_1 \equiv (h/l)^{1+[\frac{\alpha}{\sigma+1}] \frac{1}{(1-\alpha)}} \phi^{\frac{\alpha}{\sigma+1}(1-\alpha)} \zeta^{-1+[\frac{2\sigma+1}{\sigma+1}](\frac{1}{1-\alpha})] \]
Figure 4. Confidence intervals for $\epsilon$ and $\delta$ implicit in the OLS estimates of the elasticities $D_0(\epsilon, \delta)$ and $D_1(\epsilon, \delta)$ (dashed lines)

$\Rightarrow \epsilon \in [0.175; 0.378]$
Quantification of $\epsilon$ and $\zeta$ (II)

**Figure 5.** Confidence intervals for $\phi \equiv \phi_H/\phi_L$ and $\zeta \equiv \zeta_H/\zeta_L$ implicit in the OLS estimates of the intercepts $Z_0(\zeta, \phi)$ and $Z_1(\zeta, \phi)$.

With $h/l = 1.3 \Rightarrow \zeta \in [2.642; 3.915]$
The predicted growth-skill and growth-production elasticities

Table 1. Simulation results: OLS estimates of the elasticity of the predicted growth rate, $\tilde{\Gamma}$, w.r.t. the observed skill structure and predicted relative production (estimated elasticities from the observed data: $-0.026$ (s.e. 0.172) and $-0.003$ (s.e. 0.118)).

Policy implications (II)

Table 3. Counterfactual: reduction of $\zeta$ or increase in $H/L$ such that the average European share of the high-tech sector is raised to the US level (0.440 for relative production and 0.215 for relative number of firms, 1995-2007 avg).

An increase of the European growth rate by 0.1 percentage points requires a change in $H/L$ or in $\zeta$ and $\phi$ of, respectively, 35.1% or -15.4% and -27.7% $\Rightarrow$ It is more efficient for policy to target relative barriers to entry than skill structure.
We allow relative barriers to entry to comprise both an **homogeneous** and a **country-specific component**: \( \phi_i = \bar{\phi} \cdot \phi_i^c \) and \( \zeta_i = \bar{\zeta} \cdot \zeta_i^c \).
We allow relative barriers to entry to comprise both an 
\textbf{homogeneous} and a \textbf{country-specific component}: \( \phi_i = \bar{\phi} \cdot \phi_i^c \) 
and \( \zeta_i = \bar{\zeta} \cdot \zeta_i^c \).

We quantify \( \phi_i^c \) and \( \zeta_i^c \) by allowing them to be random variables 
uncorrelated with each country’s skill structure.
We allow relative barriers to entry to comprise both an **homogeneous** and a **country-specific component**: $\phi_i = \bar{\phi} \cdot \phi^c_i$ and $\zeta_i = \bar{\zeta} \cdot \zeta^c_i$.

We quantify $\phi^c_i$ and $\zeta^c_i$ by allowing them be random variables uncorrelated with each country’s skill structure.

The addition of country-specific barriers does not affect our results $\Rightarrow$ the **homogeneous component is the most relevant** to explain the observed cross-country growth-skill elasticity.

Final remarks (I)

- The effects of a country’s education policy (e.g., incentives for households to improve their educational attainment level), or say of measures to revert brain-drain flows, on economic growth may be effectively leveraged by barriers-reducing industrial policy (and vice versa);
Final remarks (I)

- The effects of a country’s education policy (e.g., incentives for households to improve their educational attainment level), or say of measures to revert brain-drain flows, on economic growth may be effectively leveraged by barriers-reducing industrial policy (and vice versa);

- The latter should aim to reduce the fixed-entry costs originating relatively larger barriers to entry in the high-tech sectors [e.g., the alleviation of the regulatory and IPR bureaucratic environment faced by technology-intensive firms or the reduction of their information and management flow fixed costs at firm creation, say through the promotion of mentoring and business-angels activities];
The effects of a country’s education policy (e.g., incentives for households to improve their educational attainment level), or say of measures to revert brain-drain flows, on economic growth may be effectively leveraged by barriers-reducing industrial policy (and vice versa);

The latter should aim to reduce the fixed-entry costs originating relatively larger barriers to entry in the high-tech sectors [e.g., the alleviation of the regulatory and IPR bureaucratic environment faced by technology-intensive firms or the reduction of their information and management flow fixed costs at firm creation, say through the promotion of mentoring and business-angels activities];

However: the effectiveness of the barriers-reducing policy is negatively related to the initial level of those barriers, which implies that barriers must be brought down to considerable low levels before they start producing significant results.
Final remarks (II)

- The role of relative barriers to entry in explaining the observed cross-country growth elasticities relies on the interaction of the homogeneous component of relative barriers with each country’s skill structure, instead of on the variability of the country-specific component of relative barriers across countries.
Final remarks (II)

- The role of relative barriers to entry in explaining the observed cross-country growth elasticities relies on the interaction of the homogeneous component of relative barriers with each country’s skill structure, instead of on the variability of the country-specific component of relative barriers across countries.
  - Regulatory costs versus non-regulatory costs?
The role of relative barriers to entry in explaining the observed cross-country growth elasticities relies on the interaction of the homogeneous component of relative barriers with each country's skill structure, instead of on the variability of the country-specific component of relative barriers across countries.

- Regulatory costs versus non-regulatory costs?
- As our data set comprises only European countries, this may be a consequence of the common, supranational, regulatory framework impinged on the EU production sectors.
The role of relative barriers to entry in explaining the observed cross-country growth elasticities relies on the interaction of the homogeneous component of relative barriers with each country’s skill structure, instead of on the variability of the country-specific component of relative barriers across countries.

- Regulatory costs versus non-regulatory costs?
- As our data set comprises only European countries, this may be a consequence of the common, supranational, regulatory framework impinged on the EU production sectors.

Our reduced-form results also suggest that a reduction of overall regulatory costs to create a business or an increase in a country’s financial development may be associated with the reduction of relative barriers to entry into the high-tech sector. Given the exploratory nature of our results in this regard, this is a topic that deserves further investigation in future work.
Thank you!
